GLASGOW G41 4SN.
9th February 2004.

Dear Mr. Marshall,

I was in telephone contact today with Mrs [redacted] and we discussed the nature and frequency of her daughter [redacted]'s asthma before and since their use of the Electromedia Model 35F (A) at home since October last year.

[redacted] had four episodes of suspected bronchiolitis between October 2002 and October 2003, which required hospitalisation, and was diagnosed as asthmatic after the last event. This was likely to have been the reason for the previous episodes. There is a family history of asthma and she has serologically confirmed house dust mite allergy.

She was prescribed steroid and beta-agonist inhalers, and also had the air-filtration apparatus installed in her bedroom. She has been remarkably improved since then, and is now only intermittently wheezy if she has a cold, which is unrelated to house dust mite allergy.

Mrs [redacted] is very encouraged by the improvement in her daughter's well-being and is delighted with the contribution that the Electromedia Model 35F (A) has made to this. She would be very reluctant to stop using this and in fact she would hope that controlling the air quality might eventually reduce her daughter's sensitisation to house dust mite and reduce her dependence on inhaled steroid therapy.

Please let me now if you require any further information.

Yours sincerely,

Charles McSharry
Principal Clinical Immunologist.

cc. Mr.P.S.B.Wood.
